6 Milestone 8: Version Pinning

 $\mathbf{21}$

Overview

This document specifies the design of a package management system for OCaml (OPAM). For the first version of OPAM, we have tried to consider the simplest design choices, even if these choices restrict user possibilities (but we hope not too much). Our goal is to propose a system that we can build in a few months. Some of the design choices might evolve to more complex tasks later, if needed.

A package management system has typically two kinds of users: end-users who install and use packages for their own projects; and packagers, who create and upload packages. End-users want to install on their machine a consistent collection of packages – a package being a collection of OCaml libraries and/or programs. Packagers want to take a collection of their own libraries and programs and make them available to other developpers.

This document describes the fonctional requirements for both kinds of users.

Conventions

In this document, \$home, \$opam, \$package and \$path are assumed to be defined as follows:

- \$home refers to the end-user home path, typically /home/thomas/ on linux, /Users/thomas/ on OSX C:\Documents and Settings\thomas\ on Windows.
- \$opam refers to the filesystem subtree containing the client state. Default directory is \$home/.opam.
- \$package refers to a path in the packager filesystem, where lives the collection of libraries and programs he wants to package.
- \$path refers to a list of paths in the packager filesystem, where lives the collection of programs (ocamlc, ocamldep, ocamlopt, ocamlbuild, ...).

User variables are written in capital letters, prefixed by \$. For instance package names will be written \$NAME, package versions \$VERSION, and the version of the ocaml compiler currently installed \$OVERSION.

1 Milestone 1: Foundations

The first milestone of OPAM focuses on providing a limited set of features, dedicated to package management of OCaml packages. OPAM rely on external tools to compile and provide full configuration options to the build tools. The goal for this first milestone is to be as much as possible compatible with any existing build system (including ocamlfind and oasis) modulo few modifications.

1.1 Client state

The client state is stored on the filesystem, under \$opam:

1.1.1 Global state

- \$opam/config is the main configuration file. It defines the OPAM version, the repository addresses and the current compiler version. The file format is described in §1.2.4.
- \$opam/opam/\$NAME.\$VERSION.opam is the OPAM specification for the package \$NAME with version \$VERSION (which might not be installed). The format of OPAM files is described in §1.2.5.
- \$opam/descr/\$NAME.\$VERSION contains the description for the version \$VERSION of package \$NAME (which might not be installed). The first line of this file is the package synopsis.
- \$opam/archives/\$NAME.\$VERSION.tar.gz contains the source archives for the version \$VERSION of package \$NAME.
- \$opam/repo/index contains the location of packages (ie. in which repositories they can be found and the priority between repositories). The file format is described in 1.2.2.

1.1.2 Compiler-specific state

All the configurations files, libraries and binaries related to the specific \$OVERSION of the OCaml compiler are stored in \$opam/\$OVERSION.

- \$opam/\$OVERSION/installed is the list of installed packages for the compiler version \$OVERSION. The file format is described in §1.2.1.
- \$opam/\$OVERSION/config/\$NAME.config is a platform-specific configuration file of for the installed package \$NAME with the compiler version \$OVERSION. The file format is described in §1.2.6. \$opam/\$OVERSION/config/ can be shortened to \$config/ for more readability.
- \$opam/\$OVERSION/install/\$NAME.install is a platform-specific package installation file for the installed package \$NAME with the compiler version \$OVERSION. The file format is described in §1.2.7. \$opam/\$OVERSION/install can be shortened to \$install/ for more readability.
- \$opam/\$OVERSION/lib/\$NAME/ contains the libraries associated to the installed package \$NAME with the compiler version \$OVERSION. \$opam/\$OVERSION/lib/ can be shortened to \$lib/ for more readability.
- \$opam/\$OVERSION/doc/\$NAME/ contains the documentation associated to the installed package NAME with the compiler version \$OVERSION. \$opam/OVERSION/doc/ can be shortened to \$doc/ for more readability.
- \$opam/\$OVERSION/bin/ contains the program files for all installed packages with the compiler version \$OVERSION. \$opam/\$OVERSION/bin/ can be shortened to \$bin/ for more readability.
- \$opam/\$OVERSION/build/\$NAME.\$VERSION/ is a tempory folder used to build package \$NAME with version \$VERSION, with compiler version \$OVERSION.\$opam/\$OVERSION/build/ can be shortened to \$build/ for more readability.

• \$opam/\$OVERSION/reinstall contains the list of packages which has been changed upstream since the last upgrade. This can happen for instance when a packager uploads a new archive or fix the OPAM file for a specific package version. Every package appearing in this file will be reinstalled (or upgraded if a new version is available) during the next upgrade when the current version of the compiler is \$OVERSION. The file format is similar to the one described in §1.2.1.

1.1.3 Repository-specific state

Configuration files for OPAM repositories REPO are stored in <code>\$opam/repo/\$REPO</code>. Repositories can be of different kinds (stored on the local filesystem, available via HTTP, available using a custom binary protocol, stored under git, . . .); they all share the same base filesystem which is initialized using the <code>opam-<kind>-init</code> script (see §1.4.1) and use only the <code>opam-<kind>-update</code> (see §1.4.2) and <code>opam-<kind>-upload</code> (see §1.4.4) scripts to exchange data between the client and the corresponding OPAM repository.

- \$opam/repo/\$REPO/kind contains the kind associated to the OPAM repository \$REPO have. The kind is stored as a single word (containing only letters and digits) and specifies which opam-<kind>-* scripts to call when updating and uploading this repository.
- \$opam/repo/\$REPO/address contains the address of the OPAM repository \$REPO. This address is passed as argument to the opam-<kind>-* scripts.
- \$opam/repo/\$REPO/opam/\$NAME.\$VERSION.opam is the OPAM specification for the package \$NAME with version \$VERSION (which might not be installed). The format of OPAM files is described in §1.2.5.
- \$opam/repo/\$REPO/descr/\$NAME.\$VERSION contains the textual description for the version \$VERSION of package \$NAME (which might not be installed). The first line of this file is the package synopsis.
- \$opam/repo/\$REPO/archives/\$NAME.\$VERSION.tar.gz contains the source archives for the version \$VERSION of package \$NAME. This folder is populated by calling the corresponding opam-<kind>-download script (see §1.4.3).
- \$opam/repo/\$REPO/updated contains the new available packages which have not yet been synchronized with the client state. This file is created by the opam-<kind>-update script (see §1.4.2). If the file empty, this means that the client state is up-to-date. The file format is the same as the one described in §1.2.1.
- \$opam/repo/\$REPO/upload/\$NAME.\$VERSION/ contains the OPAM, description and archive files to upload to the OPAM repository for the version \$VERSION of package \$NAME. The script opam-<kind>-update script (see §1.4.4) read the contents of upload/ and send it to the repository (if the repository support upload).

1.2 File syntax

1.2.1 List of packages

The following configuration files: \$opam/\$OVERSION/installed, \$opam/\$OVERSION/reinstall, and \$opam/repo/\$REPO/updated follow a very simple syntax. The file is a list of lines which contains a space-separated name and a version. Each line \$NAME \$VERSION means that the version \$VERSION of package \$NAME has been compiled with OCaml version \$OVERSION and has

been installed on the system in \$lib/\$NAME and \$bin/.

For instance, if batteries version 1.0+beta and ocamlfind version 1.2 are installed, then <code>\$opam/\$OVERSION/installed</code> will contain:

```
batteries 1.0+beta ocamlfind 1.2
```

1.2.2 Index of packages

<code>\$opam/repo/index</code> follows a very simple syntax: each line of the file contains a space separated list of words <code>\$NAME</code> <code>\$REPO</code> specifying that all the versions of package <code>\$NAME</code> are available in the OPAM repository <code>\$REPO</code>. The file contains information on all available packages (e.g. not only on the installed one).

For instance, if batteries version 1.0+beta is available in the testing repository and ocamlfind version 1.2 is available in the default and testing repositories (where default is one being used), then \$opam/repo/index will contain:

```
batteries testing ocamlfind default
```

1.2.3 General syntax

Most of the files in the client and server states share the same syntax defined in this section.

Base types The base types for values are:

- BOOL is either true or false
- STRING is a doubly-quoted OCaml string, for instance: "foo", "foo-bar", ...
- SYMBOL contains only non-letter and non-digit characters, for instance: =, <=, ... Some symbols have a special meaning and thus are not valid SYMBOLs: "() [] { } :".
- IDENT starts by a letter and is followed by any number of letters, digit and symbols, for instance: foo, foo-bar,

Compound types Types can be composed together to build more complex values:

- X Y is a space-separated pair of value.
- X | Y is a value of type either X or Y.
- ?X is zero or one occurrence of a value of type X.
- $\bullet\,$ X+ is a space-separated list of values of at least one value of type X.
- X* is a space-separated list of values of values of type X (it might contain no value).

All structured OPAM files share the same syntax:

1.2.4 Global configuration file

\$opam/config follows the syntax defined in §1.2.3 with the following restrictions:

```
<file> :=
    opam-version: "1"
    ?repositories: [ <repo>+ ]
    ocaml-version: STRING

<repo> := STRING { STRING }
```

The field repositories contains the list of OPAM repositories with their kind. The field ocaml-version corresponds to the current OCaml compiler (available in the path).

1.2.5 Package specification files: .opam

pam/pam/NAME.VERSION.opam follows the syntax defined in §1.2.3 with the following restrictions:

```
<file> :=
   opam-version: "1"
   package STRING {
     version:
               STRING
     maintainer: STRING
     ?subst: [ STRING+ ]
                [ command+ ]
     ?build:
     ?depends: <cnf-formula>
     ?conflicts: <and-formula>
     ?libraries: [ STRING+ ]
     ?syntax: [ STRING+ ]
<cnf-formula> := <cnf-formula> <cnf-formula>
               | ( <cnf-formula> )
               | <or-formula>
<or-formula> := STRING
             | STRING { <constraints> }
             | <or-formula> '|' <or-formula>
<and-formula> := STRING
```

- The first line specifies the OPAM version.
- The string after package should not contain any dot ('.') nor space ('').
- The contents of version is \$VERSION. The content of maintainer is the contact address of the package maintainer.
- The content of subst is the list of files to substitute variable (see §1.2.8 for the file format and §1.3.7 for the semantic of file substitution).
- The content of build is the list of commands to run in order to build the package libraries. The build script should build all the libraries and syntax extensions exported by the package and it should produce the platform-specific configuration and install files (e.g. \$NAME.config and \$NAME.install, see §1.2.6 and §1.2.7).
- The depends and conflicts fields contain respectively *cnf* and *and*-formulas over package names, optionally parametrized by version constraints. An expression is either:

```
- A package name: "foo";
```

- A package name with version constraints: "foo" (>= "1.2" & <= "3.4")
- A disjunction of formulas: E | F
- A conjunction of formulas: E F
- A formula between parenthesis: (E)

For instance "foo" {<= "1.2"} ("bar" | "gna" {= "3.14"}) is a valid formula whose semantic is: both any version of package "foo" lesser or equal to 1.2 and either any version of package "bar" or the version 3.14 of package "gna".

• The libraries and syntax fields contain the libraries and syntax extensions defined by the package.

1.2.6 Package configuration files: .config

pom/OVERSION/config/NAME.config follows the syntax defined in §1.2.3, with the following restrictions:

```
<file> :=
    opam-version: "1"
    <item>*
<item> := <def> | <section>
<section> :=
    <kind> STRING {
```

\$NAME.config contains platform-dependent information which can be useful for other libraries or syntax extensions that want to use libraries defined in the package **\$NAME**.

Local and global variables The definitions "IDENT: BOOL", "IDENT: STRING" and "IDENT: STRING" and "IDENT: STRING" and are used to substitute variables in template files (see §1.2.8):

- %{\$NAME:\$VAR}% will refer to the variable \$VAR defined at the root of the configuration file \$config/NAME.config.
- %{\$NAME.\$LIB:\$VAR}% will refer to the variable \$VAR defined in the library or syntax section named \$LIB in the configuration file \$config/\$NAME.config.

Library and syntax sections Each library and syntax section defines an OCaml library and the specific compilation flags to enable when using and linking with this library.

The distinction between libraries and syntax extensions is only useful at compile time to know whether the options should be used as compilation or pre-processing arguments (ie. should they go on the compiler command line or should they be passed to the -pp option). This is the responsibility of the build tool to do the right thing and the <kind> of sections is only used for documentation purposes in OPAM.

The available options are:

- asmcomp are compilation options to give to the native compiler (when using the -c option)
- bytecomp are compilation options to give to the bytecode compiler (when using the -c option)
- asmlink are linking options to give to the native compiler
- bytlink are linking options to give to the bytecode compiler
- requires is the list of libraries and syntax extensions the current block is depending on. The full list of compilation and linking options is built by looking at the transitive closure of dependencies. The contents of deps is the list of libraries or syntax extension the current section depends on. Note that we do not refer here to any package name, as multiple packages can expose libraries with the same name and interface and thus we want the user to be able to switch between them easily.

1.2.7 Package installation files: .install

\$opam/OVERSION/install/NAME.install follows the syntax defined in §1.2.3 with the following restrictions:

- Files listed under lib are copied to \$lib/\$NAME/.
- Files listed under bin are copied to \$bin/ (they can be renamed using \$SRC { \$DST }; in this case \$SRC should be a simple filename, ie. it should not start with a directory name).
- Files listed under doc are copied to \$doc/\$NAME/.
- Files listed under misc should be processed as follows: for each pair \$SRC { \$DST }, the tool should ask the user if he wants to install \$SRC to the absolute path \$DST.

1.2.8 Substitution files

All of the previous files can be generated using a special mode of opam which can perform tests and substitutes variables (see §1.3.7 for the exact command to run). Substitution files contains some templates which will be replaced by some contents. The syntax of templates is the following:

- templates such as %{\$NAME:\$VAR}% are replaced by the value of the variable \$VAR defined at the root of the file \$config/NAME.config.
- templates such as %{\$NAME.\$LIB:\$VAR}% are replaced by the value of the variable \$VAR defined in the \$LIB section in the file \$config/PACKAGE.config

1.3 Client commands

1.3.1 Creating a fresh client state

When an end-user starts OPAM for the first time, he needs to initialize **\$opam/** in a consistent state. In order to do so, he should run:

```
$ opam init [-kind $KIND] $REPO $ADDRESS
```

Where:

- \$KIND is the kind of OPAM repository (default is http);
- \$REPO is the name of the repository (default is default); and
- ADDRESS is the repository address (default is http://opam.ocamlpro.com/pub).

This command will:

- 1. Create the file \$opam/config (as specified in §1.2.6)
- 2. Create an empty \$opam/\$OVERSION/installed file, \$OVERSION is the version from the OCaml used to compile \$opam. In particular, we will not fail now if there is no ocamlc in \$path.
- 3. Initialize \$opam/repo/\$REPO by running 'opam-\$KIND-init \$ADDRESS' (see §1.4.2). If the script cannot be found in the path, the command should be canceled and should return a well-defined error.
- 4. Symlink all OPAM and description files (ie. create a symbolic link from every file in \$opam/repo/\$REPO/opam/ to \$opam/opam/ and from every file in \$opam/repo/\$REPO/descr/ to \$opam/descr/).
- 5. Create \$opam/repo/index and for each version \$VERSION of package \$NAME appearing in the repository, append the line '\$REPO \$NAME \$VERSION' to the file.
- 6. Create the empty directories \$opam/archives, \$lib/, \$bin/ and \$doc/.

1.3.2 Listing packages

When an end-user wants to have information on all available packages, he should run:

```
$ opam list
```

This command will parse \$opam/\$OVERSION/installed to know the installed packages, and \$opam/opam/*.opam to get all the available packages. It will then build a summary of each packages. The description of each package will be read in \$opam/descr/ if it exists.

For instance, if batteries version 1.1.3 is installed, ounit version 2.3+dev is installed and camomille is not installed, then running the previous command should display:

```
batteries 1.1.3 Batteries is a standard library replacement ounit 2.3+dev Test framework camomille -- Unicode support
```

1.3.3 Getting package info

In case the end-user wants a more details view of a specific package, he should run:

```
$ opam info $NAME
```

This command will parse <code>\$opam/\$OVERSION/installed</code> to get the installed version of <code>\$NAME</code>, will process <code>\$opam/repo/index</code> to get the repository where the package comes from and will look for <code>\$opam/opam/\$NAME.*.opam</code> to get available versions of <code>\$NAME</code>. It can then display:

```
package: $NAME
version: $VERSION # '--' if not installed
versions: $VERSION1, $VERSION2, ...
libraries: $LIB1, $LIB2, ...
syntax: $SYNTAX1, $SYNTAX2, ...
repository: $REPO
```

```
description:
$SYNOPSIS
$LINE1
$LINE2
$LINE3
```

1.3.4 Installing a package

When an end-user wants to install a new package, he should run:

```
$ opam install $NAME
```

This command will:

- 1. Compute the transitive closure of dependencies and conflicts of packages using the dependency solver (see §1.3.11). If the dependency solver returns more than one answer, the tool will ask the user to pick one, otherwise it will proceed directly. The dependency solver should also mark the packages to recompile.
- 2. The dependency solver sorts the collections of packages in topological order. Then, for each of them do:
 - (a) Check whether the package is already installed by looking for the line \$NAME \$VERSION in \$opam/\$OVERSION/installed. If not, then:
 - (b) Look into the archive cache to see whether it has already been downloaded. The cache location is: \$opam/archives/\$NAME.VERSION.tar.gz
 - (c) If not, process <code>\$opam/repo/index/</code> to get the repository <code>\$REPO</code> where the archive is available, get the repository kind by looking at <code>\$opam/repo/\$REPO/kind</code> and then ask the repository to download the archive by calling <code>opam-\$KIND-download</code> (see §1.4.3).

Once this is done, symlink the archive in \$opam/archives.

- (d) Decompress the archive into \$build/\$NAME.\$VERSION/.
- (e) Substitute the required files.
- (f) Run the list of commands to build the package with \$bin in the path.
- (g) Process \bullet uild/ \bullet NAME. \bullet VERSION/ \bullet NAME.install to install the created files. The file format is described in $\S 1.2.7$.
- (h) Install the installation file \$build/\$NAME.\$VERSION/\$NAME.install in \$install/ and the configuration file \$build/\$NAME.\$VERSION/\$NAME.config in \$config/.

1.3.5 Updating index files

When an end-user wants to know what are the latest packages available, he will write:

\$ opam update

This command will follow the following steps:

- For each repositories in **\$opam/config**, run the appropriate **opam-\$KIND-update** script (see §1.4.2).
- For each repositories in <code>\$opam/config</code>, process <code>\$opam/repo/\$REPO/updated</code> and update <code>\$opam/repo/index</code>, <code>\$opam/opam/</code> and <code>\$opam/desc</code> accordingly (ie. add the right lines in <code>\$opam/repo/index</code> and create the missing symlinks). Here, the order in which the repositories are specified is important: the first repository containing a given version for a package will be the one providing it (this can be changed manually by editing <code>\$opam/repo/index</code> later).
- For each line \$REPO \$NAME \$VERSION in \$opam/repo/index, if the version \$VERSION of package \$NAME has been modified upstream (ie. if the line \$NAME \$VERSION appears in \$opam/repo/\$REPO/\$updated) and if the package is already installed (ie. it appears in opam/\$OVERSION/installed), then update \$opam/\$OVERSION/reinstall accordingly (for each compiler version \$OVERSION).

Packages in \$opam/\$OVERSION/reinstall will be reinstalled (or upgraded if a new version is available) on the next opam upgrade (see §1.3.6), with \$OVERSION being the current compiler version when the upgrade command is run.

• Delete each \$opam/repo/\$REPO/\$updated

1.3.6 Upgrading installed packages

When an end-user wants to upgrade the packages installed on his host, he will write:

```
$ opam upgrade
```

This command will:

- Call the dependency solver (see §1.3.11) to find a consistent state where **most** of the installed packages are upgraded to their latest version. Moreover, packages listed in \$opam/\$OVERSION/reinstall will be reinstalled (or upgraded if a new version is available). It will install each non-installed packages in topological order, similar to what it is done during the install step, See §1.3.4.
- Once this is done the command will delete **\$opam/\$OVERSION/reinstall**.

1.3.7 Getting package configuration

The first version of OPAM contains the minimal information to be able to use installed libraries. In order to do so, the end-user (or the packager) should run:

```
$ opam config -list-vars
$ opam config -var $NAME:$VAR
$ opam config -var $NAME.$LIB:$VAR
$ opam config -subst $FILENAME+
$ opam config [-r] -I $NAME+
$ opam config [-r] -bytecomp $NAME.$LIB+
$ opam config [-r] -asmcomp $NAME.$LIB+
$ opam config [-r] -bytelink $NAME.$LIB+
$ opam config [-r] -asmlink $NAME.$LIB+
```

- -list-vars will return the list of all variables defined in installed packages (see §1.2.6)
- -var \$var will return the value associated to the variable \$var
- -subst \$FILENAME replace any occurrence of %{\$NAME:\$VAR}% and %{\$NAME.\$LIB:\$VAR}% as specified in §1.2.8 in \$FILENAME.in to create \$FILENAME.
- -I \$NAME will return the list of paths to include when compiling a project using the package \$NAME (-r gives a result taking into account the transitive closure of dependencies).
- -bytecomp, -asmcomp, -bytelink and -asmlink return the associated value for the section \$LIB in the file \$config/\$NAME.config (-r gives a result taking into account the transitive closure of all dependencies).

1.3.8 Uploading packages

When a packager wants to create a package, he should:

- 1. create \$package/\$NAME.\$VERSION.opam containing in the format specified in §1.2.5.
- 2. create a file describing the package
- 3. make sure the build scripts:
 - build the libraries and packages advertised in \$package/\$NAME.\$VERSION.opam
 - generates a valid \$package/\$NAME.install containing the list of files to install (the file format is described in 1.2.7).
 - generates a valid **package/**NAME.config containing the configuration flags for libraries exported by this package (the file format is described in 1.2.6).
- 4. create an archive \$NAME.\$VERSION.tar.gz with the sources he wants to distribute.
- 5. run the following command:
 - \$ opam upload -opam \$OPAM -descr \$DESCR -archive \$ARCHIVE -repo \$REPO

This command will parse \$0PAM to get the package name and version and it will:

- move \$OPAM to \$opam/repo/\$REPO/upload/\$NAME.\$VERSION.opam
- move \$DESCR to \$opam/repo/\$REPO/descr/\$NAME.\$VERSION
- move \$ARCHIVE to \$opam/repo/\$REPO/archives/\$NAME.\$VERSION.tar.gz

It will then call opam-\$KIND-upload to upload the files upstream (see $\S1.4.4$).

This command will work only for writable repositories; in case of errors (for instance if the repository is read-only) the script returns a non-zero exit code and stores the error message in <code>sopam/repo/\$REPO/error</code> (see §1.4.5).

1.3.9 Removing packages

When the user wants to remove a package, he should write:

```
$ opam remove $NAME
```

This command will check whether the package \$NAME is installed, and if yes, it will display to the user the list packages that will be uninstalled (ie. the transitive closure of all forward-dependencies). If the user accepts the list, all the packages should be uninstalled, and the client state should be let in a consistent state.

1.3.10 Managing OPAM repository

When the user wants to manage OPAM repositories, he should write:

```
$ opam repository -list
$ opam repository -rm $REPO
$ opam repository -add [-kind $KIND] $REPO $ADRESS
```

- -list lists the current repositories by looking at <code>\$opam/config</code>
- -rm \$REPO deletes \$opam/repo/\$REPO and removes \$REPO from the repositories list in \$opam/config. Then, for each package in \$opam/repo/index it updates the link between packages and repositories (ie. it either deletes packages or symlink them to the new repository containing the package).
- -add [-kind \$KIND] \$REPO \$ADDRESS initializes \$REPO as described in §1.3.1.

1.3.11 Dependency solver

Dependency solving is a hard problem and we do not plan to start from scratch implementing a new SAT solver. Thus our plan to integrate (as a library) the Debian depency solver for CUDF files, which is written in OCaml.

- the dependency solver should run on the client; and
- the dependency solver should take as input a list of packages (with some optional version information) the user wants to install, upgrade and remove and it should return a consistent list of packages (with version numbers) to install, upgrade, recompile and remove.

1.4 OPAM repository scripts

As stated above, OPAM repositories can be of different kinds. A given kind \$KIND has associated scripts opam-\$KIND-init, opam-\$KIND-update, opam-\$KIND-download and opam-\$KIND-upload which should behave in the way specified below.

1.4.1 Init script

```
$ opam-$KIND-init $ADDRESS
```

This script should contact the OPAM repository located at address \$ADDRESS and populate its local state (ie. ./opam/, ./descr/ and archives) as specified in §1.1.3.

1.4.2 Update script

\$ opam-\$KIND-update \$ADDRESS

This script should get the list of newly available packages, by contacting the OPAM repository located at address \$ADDRESS and update \$./opam and ./descr.

It should then create (or update) ./updated to reflect the newly available packages and the one who changed uptstream..

1.4.3 Download script

\$ opam-\$KIND-download \$ADDRESS \$NAME.\$VERSION

This script should get \$NAME.\$VERSION.tar.gz from the OPAM repository located at address ADDRESS and store it into \$opam/repo/\$REPO/archives/ (this should overwrite any previously existing file if one is already there).

1.4.4 Upload script

\$ opam-\$KIND-init \$opam/repo/\$REPO

This script should send the contents of <code>\$opam/repo/\$REPO/upload/</code> to the repository whose address is stored in <code>\$opam/repo/\$REPO/address</code> and remove the folder contents when it's done.

1.4.5 Error handling

In case any of the above scripts return with a non-zero exit code, the full error message will be stored into opam/repo/\$REPO/error

1.4.6 RSYNC repository

The first Milestone includes the necessary scripts to support rsync repositories. In order to do so:

- The OPAM repository is a filesystem similar to what is described in <code>\$opam/repo/\$REPO</code>.
- opam-rsync-init \$PATH \$ADDRESS simply runs something like:
 - \$ cd \$PATH && rsync [..] \$ADDRESS/opam && rsync [..] \$ADDRESS/descr
- opam-rsync-download \$PATH \$NAME \$VERSION will simply run something like:
 - \$ cd \$PATH && rsync [..] \$ADDRESS/archives/\$NAME.\$VERSION.tar.gz
- opam-rsync-update \$PATH will also run rsync and filter the command output to populate \$opam/repo/\$REPO/updated accordingly.
- opam-rsync-upload \$PATH will return an error if the OPAM repository is not writable (for instance if the repository if an HTTP server). In this case the server state can be updated manually by copying the new files in the right place on the server filesystem.

2 Milestone 2: OPAM server

The only OPAM repository kind available in Milestone 1 is rsync.

This second milestone describes a new kind of repository: server. The OPAM server uses a custom binary protocol between a client (the opam-server-* scripts) and a server (opam-server which is run on the server). This is intended to be the preferred way to upload new packages to OPAM repositories as it does not requires any external authentification mechanisms.

2.1 Server state

In this section, **\$opamserver** refers to the filesystem subtree containing the server state. Default directory is **\$home/.opam-server**. The state is similar to what is described in §1.1.1:

- \$opamserver/opam/\$NAME.\$VERSION.opam is the OPAM specification for the package \$NAME with version \$VERSION (which might not be installed). The format of OPAM files is described in §1.2.5.
- \$opamserver/descr/\$NAME.\$VERSION contains the description for the version \$VERSION of package \$NAME (which might not be installed). The first line of this file is the package synopsis.
- \$opamserver/archives/\$NAME.\$VERSION.tar.gz contains the source archives for the version \$VERSION of package \$NAME.

2.2 Binary Protocol

The protocol is very simple, there is one kind of messages corresponding to each basic client actions (which will be used by the <code>opam-server-*</code> scripts). The only "complex" parts resides in the basic authentication mechanisms: the server stores a key for each package (every version shares the same key); the key is sent to the client the first time a new package is uploaded and key consistency is checked each time a new version of the package is uploaded.

- Communication between clients and servers always start by an hand-shake to agree on the protocol version.
- All the basic values (names, versions and binary data) are represented as in OCaml strings and are marshaled as an 64-bits integer (the string size) followed by the string contents.
- Messages are marshaled using a simple binary protocol: the first byte represents the message number, and then each string argument is stacked sequentially. The list of messages from the client to server is:

#	Client-to-Server Message	Contents	Description	
0	ClientVersion	version: string	Send the client version to the server	
1	GetList	_	Ask for the list of all available OPAM files	
2	GetOPAM	name : string Ask for the binary representation of		
		version: string	a given OPAM file	
3	GetDescr	name : string	name : string Ask for the binary representation of	
		version: string	a given description file	
4	GetArchive	name : string	Ask for the binary representation of	
		version: string	a given archive file	
5	NewPackage	name : string	Create a new package on the server.	
		version: string	The client should provide the OPAM and	
		opam : string	descr files and the source archive.	
		descr : string		
		archive: string		
6	NewVersion	name : string	Upload a new version of an already existing	
		version: string	package on the server. The client	
		opam : string	should also provide a security key	
		descr : string		
		archive: string		
		key : string		

• Answers from the server are encoded in the same way (ie, a byte for the message number, followed by the sequential marshaling of the arguments). Pairs are stacked sequentially. List are encoded by stacking first the list length in a 64-bit integer and then all the elements of the list in sequential order. The list of messages from servers to clients is:

#	Server-to-Client Message	Contents	Description
0	ServerVersion	version: string	Return the server version
1	PackageList	list : (string*string) list	Return the list of available
			package names and versions
2	OPAM	opam : string	Return an OPAM file
3	Descr	descr : string	Return an OPAM file
4	Archive	archive: string	Return an archive file
5	Key	key : string	Return a security key
6	OK	_	The update went OK
7	Error	error : string	An error occurred

Note that when an error is raised by an arbitrary function at server side, the client receives Error.

2.3 Server authentication

The server should be able to ask for basic credential proofs. The protocol can be sketched as follows:

- packagers store keys in <code>\$opam/keys/NAME</code>. These keys are random strings of size 128.
- the server stores key hashes in \$opamserver/hashes/NAME.
- when a packager uploads a fresh package the server returns a random key. Clients then stores that key in \$opam/keys/NAME.
- when a packager wants to upland a new version of an existing package, the client also sends the key. The server then checks whether the hash of the key is equal to the one

stored in **Sopamserver/hashes/NAME**; if yes, it updates the package and return **OK**, if no if it returns an **Error**.

2.4 Scripts

The initialization script: opam-server-init, the update script: opam-server-update, the download script: opam-server-download and the upload script:opam-server-upload will work as expected, using the binary protocol defined in §2.2 in order to correctly update the client state as defined in §1.4.

3 Milestone 3: Multiple compiler versions

This milestone focus on the support of multiple compiler versions.

3.1 Compiler Description Files

For each compiler version OVERSION, the client state will be extended with the following files:

• \$opam/compilers/OVERSION.comp

The syntax of .comp files follows the one described in §1.2.3 with the following restrictions:

```
<file> :=
   opam-version: "1"
   src:
               STRING
               [STRING+]
   make:
   ?patches: [ STRING+ ]
   ?configure: [ STRING+ ]
   ?bytecomp: [ STRING+ ]
   ?asmcomp:
               [STRING+]
   ?bytelink: [ STRING+ ]
   ?asmlink: [ STRING+ ]
   ?packages: [ STRING+ ]
   ?requires: [ STRING+ ]
   ?pp:
               [ <ppflag>+ ]
<ppflag> := CAMLP4 { <dep>+ }
          | <flag>
```

- src is the location where this version can be downloaded. It can be:
 - an archive available in the local filesystem
 - an archive available via http or ftp
 - a version-controlled repository under svn or git (with the expectation that these tools are installed on the user host).
- patches are optional patch addresses, available via http, ftp or locally on the filesystem.

- configure are the optional flags to pass to the configure script. The order is relevant: -prefix=\$opam/OVERSION/ will be automatically added at the end to these options. Remark that if these flags contain -bindir, -libdir, and -mandir, then every -prefix will be ignored by configure.
- make are the flags to pass to make. It must at least contain some target like world or world.opt.
- packages is the list of packages
- bytecomp, asmcomp, bytelink and asmlink are the compilation and linking flags to pass to the OCaml compiler. They will be taken into account by the opam config command (see §1.3.7).
- packages is the list of packages to install just after the compiler installation finished. These libraries will not consider what is in the requires nor pp (as requires and pp might want to use things already installed with packages).
- requires is a list of libraries and syntax extensions dependencies which will be added to every packages installed with this compiler. The libraries and syntax extensions should be present in packages defined in packages, othewise an error should be thrown.
- pp is the command to use with the -pp command-line argument. It is either a single flag or a camlp4 command, such as CAMLP4 [pp-trace]: this will look for the compilation flags for the syntax extension pp-trace and expand the camlp4 command-line accordingly. All the packages should be present in packages.

For instance the file, 3.12.1+memprof.comp describes OCaml, version 3.12.1 with the memory profiling patch enabled:

```
src: "http://caml.inria.fr/pub/distrib/ocaml-3.12/ocaml-3.12.1.tar.gz"
make: [ "world" "world.opt" ]
patches: [ "http://bozman.cagdas.free.fr/documents/ocamlmemprof-3.12.0.patch" ]
```

And the file trunk-g-notk-byte.comp describes OCaml from SVN trunk, with no tk support and only in bytecode, and all the libraries built with -g:

```
src: "http://caml.inria.fr/pub/distrib/ocaml-3.12/ocaml-3.12.1.tar.gz"
configure: [ "-no-tk" ]
make: [ "world" ]
bytecomp: [ "-g" ]
bytelink: [ "-g" ]
```

3.2 Switching compiler version

If the user wants to switch to an other compiler version, he should run:

```
$ opam switch [-clone] $OVERSION
```

This command will:

• Look for an existing \$opam/\$OVERSION directory.

- If it exists, then change the ocaml-version content to \$OVERSION in \$opam/config.
- If it does not exist, look for an existing <code>\$opam/compilers/OVERSION.comp</code>. If the file does not exists, the command will fail with a well-defined error.
- If the file exist, then build the new compiler with the right options (and pass --prefix \$opam/\$OVERSION to ./configure) and initialize everything in \$opam/ in a consistent state as if "opam init" has just been called.
- If the -clone option is set, the command will try to install the packages that were installed before switching (that are not currently installed). In case the new version contains installed packages that were not installed before switching, it will try to keep them.

In short, the heuristic is to install the maximum of previous packages and remove the minimum. The success depends on the compatibility of the existing packages with respect to this new \$OVERSION.

4 Milestone 4: OPAM and git

- 4.1 OPAM repository under git
- 4.2 Package repository under git
- 5 Milestone 9: Parallel Build
- 6 Milestone 8: Version Pinning
